1.0 Introduction

Asthma is a chronic inflammatory disorder characterized by variable and recurring symptoms of airflow obstruction that manifest secondary to bronchoconstriction, airway hyper-responsiveness, and airway edema, which tend to occur in response to a variety of stimuli. Asthma exacerbations are a leading cause of hospitalization in children.

The hallmark of asthma exacerbation management involves optimizing bronchodilation and decreasing airway inflammation. While these elements are generally well-practiced, there continues to be significant variability in practice which can hinder optimal management and increase the duration of acute symptoms. Furthermore, inconsistencies in asthma teaching and associated preventative recommendations that are given to families have been reported, which lead to confusion, patient and caregiver dissatisfaction, and poor asthma control. It is therefore essential that consistent and thorough asthma education be provided and prevention strategies initiated while in hospital with appropriate post discharge follow up in the community.

The recommendations presented in this guideline and the associated pathway have been created using an interdisciplinary panel of experts and key users following extensive review of the literature, existing guidelines, and benchmarking with other reputable institutions.

Objectives

In the target population, the objectives of this guideline are to:

- Streamline the medical management of inpatients admitted to Paediatric Medicine with an acute asthma exacerbation;
- Improve appropriate diagnostic testing;
- Provide optimal pharmacotherapy to prevent or minimize adverse effects of therapy;
- Achieve appropriate length of stay by establishing a standard salbutamol-weaning protocol;
- Standardize and promote effective asthma teaching using an asthma checklist;
- Ensure appropriate ongoing asthma management through initiating and adhering to an asthma action plan;
- Prevent recurrent asthma exacerbations and minimize the need for Emergency Department visits and/or hospitalizations secondary to poor asthma control by ensuring appropriate follow-up;
- Ensure appropriate targets are met for discharge to minimize readmission rates (i.e., spirometry);
- Ensure access to medications to prevent readmissions; and
- Enhance appropriate utilization of community resources and ensure appropriate follow up.
Target Users

Include, but are not limited to:

- Inpatient physicians, nurses, nurse practitioners, and trainees
- Respiratory Therapists
- Pharmacists
- Patients and families

2.0 Clinical Recommendations

Target Population:

- **Inclusion:** This management pathway is intended primarily for use in children age > 12 months of age being admitted to hospital with an acute asthma exacerbation.
- **Exclusion:** This pathway is not intended for use in children with:
  - Congenital or acquired cardiovascular disease
  - Cystic fibrosis
  - Chronic lung disease or bronchopulmonary dysplasia
  - Immunodeficiency syndromes
  - Sickle Cell Disease
  - Multiple co-morbidities
  - Severe symptoms requiring management in an ICU setting
  - A condition requiring treatment with a beta-blocker

Diagnosis:

- Asthma can be diagnosed in children > 1 year old
- In school-aged children > 6 years old and adolescents, prior diagnosis of asthma using pulmonary function tests is ideal
- In children 1 to 5 years of age, the diagnosis of asthma should be considered in children with ≥ 2 wheezing episodes or frequent (≥ 8 days/month) wheeze symptoms
  - Diagnosis requires documentation of or convincing parent report of signs or symptoms of airflow obstruction and improvement or reversibility of obstruction with asthma therapy and no suspicion of an alternative diagnosis

Assessment:

- Thorough clinical history should include:
  - Time of onset of exacerbation
Inpatient Management of Acute Asthma Exacerbation

- All current medications and time of last dose and use of aerochamber
- Estimated number of asthma-related visits and severity (office, ED, hospitalizations, and ICU admissions/need for intubation)
- Severity of symptoms compared to previous exacerbations
- Response to treatments prior to admission
- Last course of systemic steroids
- Ability to access medications (drug plan)
- Assessment of persistent symptoms: use of salbutamol, nighttime symptoms, and exercise intolerance
- Presence of complicating illnesses (pulmonary, cardiac)
- Diseases aggravated by steroid therapy (diabetes, hypertension, ulcers, psychosis)
- Potential triggers for exacerbation
- History of food allergy or allergy
- Cigarette smoke exposure - maternal, paternal, caregiver
- Social and environment history-crowding in home, exposure to irritants

- Physical examination should include but is not limited to:
  - Assess the overall severity of the exacerbation using: (Respiratory Assessment Criteria)
    - Vital signs and pulse oximetry
    - Level of alertness
    - Ability to speak in sentences
    - Degree and quality of wheezing/aeration
    - Presence of signs suggestive of increased work of breathing
    - Presence of cyanosis/pallor
  - Assessment of hydration status
  - Signs suggestive of complications (pneumothorax, pneumomediastinum, pneumonia) or of upper airway obstruction (croup, foreign body, etc.)

Diagnostic Tests:
- Blood work, nasopharyngeal swabs, and chest imaging are NOT recommended for routine management of a patient with an acute asthma exacerbation
  - Consider checking serum potassium in patients who are receiving Ventolin Q1h for 6 hours or less for a prolonged period of time
  - Consider checking blood gases in patients who are in severe respiratory distress that are not improving with treatment
  - Consider nasopharyngeal swab if high suspicion for influenza with intention to start Tamiflu if positive or on patients with severe asthma for whom the asthma escalation pathway has been initiated.
  - Consider chest imaging in patients who fail to respond to treatment in 48 hours, develop increasing oxygen requirements, develop a new fever that in is not explained by the physical examination, or have an atypical asthma exacerbation presentation without a previous chest x-ray
- Spirometry should be ordered for children ≥ 8 years old once stable during admission in order to provide an objective comparison measure of lung function. If the FEV₁ < 40, consult Respiratory Medicine to ensure adequate follow up with a respirologist
### Alternative treatments:

- The following treatments are **NOT** routinely recommended for asthma management:
  - Methylxanthines
  - Antibiotics except as needed for comorbid conditions
  - IV hydration unless unable to safely maintain oral hydration
  - Chest physical therapy
  - Mucolytics
  - Sedation

### Management

<table>
<thead>
<tr>
<th>Basic Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>The basic inpatient management of an acute asthma exacerbation involves bronchodilators, decreasing airway inflammation, supportive care to ensure that the patient is clinically stable, well oxygenated, and well hydrated, and the initiation of interventions (asthma prevention therapy and asthma teaching) to reduce the risk of future exacerbations.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Assessment of Asthma Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>- There are no asthma severity scoring tools that have been validated for use in the inpatient setting.</td>
</tr>
<tr>
<td>- Using the best available evidence, the consensus of the Guideline Committee was to use the Respiratory Assessment Criteria adapted from the Children's Hospital of Philadelphia to assess Asthma Severity and direct pathway interventions accordingly.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Oxygen Therapy</th>
</tr>
</thead>
<tbody>
<tr>
<td>- There is a lack of evidence to specify an oxygen saturation (by pulse oximetry) threshold below which supplemental oxygen is indicated. The consensus of the guideline committee using best available evidence recommends starting supplemental oxygen when the saturation is <strong>consistently</strong> &lt; 88% while breathing room air.</td>
</tr>
<tr>
<td>- Intermittent oxygen saturation monitoring should be used for any child not requiring continuous oxygen therapy.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bronchodilator therapy</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Salbutamol is the bronchodilator of choice and frequency of administration should reflect the respiratory assessment criteria.</td>
</tr>
<tr>
<td>- Administration of salbutamol is recommended using a metered dose inhaler (MDI) with an appropriate-sized spacer and mask (if under 4 years old).</td>
</tr>
<tr>
<td>- Administration via an MDI and spacer is better tolerated, associated with decreased adverse effects, decreased length of stay, and has been found to be more effective at medication administration than a nebulizer</td>
</tr>
<tr>
<td>- Use of a nebulizer may be considered in managing patients with severe respiratory distress and impending respiratory failure who may require continuous or passive medication administration with concurrent high flow oxygen administration</td>
</tr>
</tbody>
</table>
Steroid Therapy

- Systemic corticosteroids are essential in the treatment of the acute asthma exacerbation
- Dexamethasone, Prednisone, Prednisolone, and IV Methylprednisolone are frequently used medications in the management of patients with an acute asthma exacerbation
  - There is a lack of evidence to suggest that the use of any of these medications is superior to the others. The consensus of the Guideline Committee is to recommend a 2-day course of dexamethasone for the treatment of the routine acute asthma exacerbation. Considerations included were palatability, duration of treatment, half-life, side effects, and cost to families.
- Inhaled corticosteroids (ICS) are not as effective as PO or IV steroids for the acute management of exacerbations and should not be used for this purpose.

Ipratropium Bromide

- There is no evidence to support the inpatient use of ipratropium to manage acute asthma exacerbations.

IV Magnesium Sulphate

- Consider the use of IV magnesium sulphate in cases of severe asthma that do not appear to be improving despite aggressive management with bronchodilator and corticosteroid therapy

Asthma Prevention Strategy

- ICS are critical in the long-term control of asthma symptoms and should be started or restarted at discharge following the course of systemic corticosteroids
  - In line with the Canadian Paediatric Society’s recommendations, the Guideline Committee recommends a 12-week trial of a medium daily dose of ICS
- Asthma education is a key part of prevention and is a fundamental element in inpatient management. The Guideline Committee recommends that the Asthma Teaching Checklist and Action Plan are reviewed thoroughly prior to discharge with ongoing utilization of these resources in the community with their primary care provider.

Monitoring and Progression through the Pathway:

- Repeated clinical assessment should be conducted based on Respiratory Assessment Criteria and Bedside PEWS criteria for monitoring
- Weaning of salbutamol is based on asthma severity
- Seek medical reassessment for patients who are worsening or whose symptoms persist despite aggressive management
- CCRT should be consulted and the Asthma Escalation Pathway initiated for patients with severe asthma who require salbutamol < Q1hourly and/or have increasing oxygen requirements
- Spirometry should be ordered for children ≥ 8 years old prior to discharge
  - If spirometry cannot be obtained prior to discharge in the laboratory, consider bedside spirometry performed by respiratory therapists

Discharge and Follow Up:

- The interdisciplinary team should begin discharge planning on admission
- Discharge planning involves initiation of ICS once acute management is complete, ensuring teaching has been
performed, and establishing follow up plans with an asthma action plan in place

- The Guideline Committee recommends follow up within 72 hours of discharge for reassessment of acute symptoms
- Referral to an Outpatient Asthma Clinic is recommended for all patients discharged from hospital

PRINTABLE VERSION OF SUMMARY OF INPATIENT ASTHMA ASSESSMENT, MANAGEMENT, MONITORING, AND DISCHARGE CRITERIA
Inpatient Management of Acute Asthma Exacerbation

Inpatient Asthma Exacerbation Management

History to Include:
- Time of onset of exacerbation
- Severity of symptoms compared to previous exacerbations
- Response to treatments prior to admission
- All current medications, lines of care and dose
- Last course of systemic steroids
- Estimate duration of current/related past exacerbations
- O2 and CO2 static, hospitalization, and/or admitted to hospital for intubation
- Presence of complicating diseases, hypertension, CHF, preeclampsia

Physical exam to include:
- Assess the severity of the exacerbation
- Vital signs and pulse oximetry
- Level of consciousness
- Presence of cyanosis
- Presence of retractions
- Presence of stridor
- Presence of inspiratory or expiratory wheezing
- Presence of inspiratory or expiratory chest wall in motion
- Presence of cor pulmonale
- Presence of nasal flaring
- Presence of tracheal tug
- Presence of respiratory distress
- Presence of expiratory prolongation
- Presence of tachypnea
- Presence of wheezing

Respiratory Assessment Criteria (RAC)

1. Use Respiratory Assessment Criteria (RAC) to determine asthma severity
2. Assign the child to most severe category in which any parameters are met
3. Administer Systemic Steroids: Decadron 0.6 mg/kg x 2 doses (total) as per formulary

Complete Initial Assessment and Management including:
- History and physical examination
- Admission Or: if SpO2 ≤ 92%
- Inability to tolerate PD or in severe category, consider 10: Methylnaphedrines, reasons in 24 hrs as per formulary

Mild
- Salbutamol: Inhaled GII as metered dose inhaler (MDI) as per formulary
- Reassessment: GII using RAC

Moderate
- Salbutamol: Inhaled GII x 2 as per formulary
- Reassessment: GII using RAC

Severe
- Salbutamol dosage: Inhaled GII when ≥ 2 then GII via MDI (consider nebulized) as per formulary
- Reassessment: GII using RAC; then GII, MDI in reassess, 11 receiving Salbutamol GII x 6 hours

Considerations:
- Checking serum potassium
- Estimating IV access
- NPO status (administer GII NG plus 300mg/kg KCL if NPO)
- If patient continues to require ≥ GII Salbutamol consult CCRT and refer
- Asthma Education/Programming for further management

Discharge Instructions:
- Salbutamol Inhaler GII x 24 hrs then as needed GII PRN as per formulary
- Instruct patient to avoid corticosteroids (e.g. Prednisone) for 12 weeks (in total) as per formulary
- Complete systemic steroid course (total 2 days Decadron or 2 doses Prednisolone) as per formulary
- Review Positive: Asthma Action Plan
- Review MCC asthma management protocol
- Review MCC asthma protocol technique (revisions provided from SickKids)
- Ensure family knows to see primary care physician within 72 hours of discharge for reassessment
- Refer to SickKids Outpatient Asthma Clinic is recommended for all patient discharged from the hospital
- If ≥ 6 years old, symptom to be completed (in tile or bedside), consult Respiratory Medicine if FEF25-75

Patient discharged home with appropriate follow-up

3.0 Implementation and Evaluation Plan

Implementation Plan

- Education and awareness building by the Paediatric Medicine Division's practice champions during resident/fellow orientation, resident educational rounds, and nursing orientation/staff meetings/situational bedside teaching.
- Inpatient Medical Director to communicate updates in practice to the Division of Paediatric Medicine.
- Lead respiriologists to communicate updates in practice to the Division of Respirology
- E-formulary to be updated to reflect recommended medications and dosing.

Evaluation Plan

- Compare baseline pre-implementation and post-implementation data for Paediatric Medicine:
  - Number (#) of patients admitted with acute asthma exacerbations from the Emergency Department to the Paediatric Medicine inpatient wards;
  - Average length of stay of patients admitted with acute asthma exacerbations;
  - # of patients admitted to Paediatric Medicine that required transfer to the PICU;
  - # of patients readmitted with acute asthma exacerbations within 7 days of discharge from the hospital;
  - # of patients representing to the Emergency Department within 48 hours of discharge with recurrence of asthma symptoms;

4.0 Guideline Group and Reviewers

Guideline Group Membership:

1. Aliya Jaffer, Nurse Practitioner, Division of Paediatric Medicine
2. Iris Liu, Nurse Practitioner, Division of Paediatric Medicine
3. Dr. Sanjay Mahant, Staff Physician, Division of Paediatric Medicine
4. Dr. Laila Premji, Staff Physician, Division of Paediatric Medicine
5. Dr. Michael Weinstein, Staff Physician, Division of Paediatric Medicine
6. Dr. Padma Subbarao, Staff Physician, Division of Paediatric Respiratory Medicine
7. Dr. Theo Moraes, Staff Physician, Division of Paediatric Respiratory Medicine
8. Adelina Morra, Nurse Educator, Asthma Clinic & Division of Paediatric Medicine
9. Susan Balkovec, Asthma Educator, Paediatric Respiratory Medicine
10. Jas Otal, Clinical Pharmacist, Division of Paediatric Medicine
11. Andrew Joaquin, Clinical Pharmacist, Division of Paediatric Medicine
12. Gaaya Thurairajah, Nursing Team Lead, Streamlined Care Unit
13. Amy Sawyer, Nursing Team Lead, Streamlined Care Unit
14. Carolyn Jeffs, Nursing Team Lead, Streamlined Care Unit
