**Sticker syndrome** is a connective tissue disorder that includes hearing loss that is both conductive and sensorineural (the degree of hearing loss varies among affected individuals and may become more severe over time); ocular findings of myopia, cataract and retinal detachment; distinctive facies that include midfacial underdevelopment and cleft palate (often apart of the Robin sequence). Most individuals with Sticker syndrome have skeletal abnormalities that affect the joints. The joints of affected children and young adults may be loose and very flexible (hypermobile), though joints become less flexible with age. Arthritis often appears early in life and may cause joint pain or stiffness. Problems with the bones of the spine (vertebrae) may also occur, including abnormal curvature of the spine (scoliosis or kyphosis) and flattened vertebrae (platyspondyly). These spinal abnormalities may cause back pain. Variable phenotypic expression of Sticker syndrome occurs both within and among families.

The genes associated with Sticker syndrome are involved in the production of three types of collagen: type II, type IX and type XI. Collagens are molecules that provide structure and strength to connective tissues that support the body’s joints and organs. These collagens are components of vitreous, cartilage and other connective tissues.

A similar condition called Marshall syndrome is characterized by a distinctive facial appearance, eye abnormalities, hearing loss, and early onset arthritis. Marshall syndrome can also include short stature, which is typically not seen in Sticker syndrome.

**Genetics**

Sticker syndrome can be inherited in an autosomal dominant (AD) or autosomal recessive (AR) fashion. 80-90% of all cases of Sticker syndrome are associated with AD variants in the COL2A1 gene. The targeted Next Generation Sequencing (NGS) panel described below includes genes associated with both modes of inheritance.

**Test Methods**

Complete sequencing of the coding region and flanking intron/exon boundaries of the genes listed below. This is done via NGS of the six gene Sticker syndrome targeted gene panel. Please refer to our “A Guide to Next-Generation Sequencing” information sheet available on our website, for further details.

**Interpretation of Test Results**

Genetic testing may reveal one or more variants in the Sticker syndrome genes, which should be interpreted in the context of the suspected clinical diagnosis, inheritance pattern, clinical findings, family history and other experimental data.

Please refer to our “A Guide to Interpreting Sequence Variations” information sheet available on our website, for further details.

**WHO SHOULD BE TESTED?**

- Individuals clinically suspected of being affected with Sticker syndrome.
- Relatives of a proband with identified pathogenic variant(s) in an Sticker syndrome-associated gene.
- Pregnancies at increased risk due to a family history of a Sticker syndrome.
